```
Transition Rate Matrix: Q, infinitesimal
generator of \boldsymbol{H}(t). \boldsymbol{H}(t) = e^{\boldsymbol{Q}t}.
Diagonal Elements \leq 0.
q_{ii} = \lim_{\Delta t \to 0} \left[ \frac{p_{ii}(\Delta t) - 1}{\Delta t} \right].
Off-Diagonal Elements \geq 0.
\begin{array}{l} q_{ij} = \lim_{\Delta t \to 0} [\frac{p_{ij}(\Delta t) - 0}{\Delta t}], \text{ for } i \neq j. \\ \text{In each row, sum of off-diagonal} = \text{magnitude of} \end{array}
diagonal: q_{ii} = -\sum_{i \neq j} q_{ij}
State Probabilities:
\pi(t) = \pi(0) H(t), \ \pi(t) = \pi(0) e^{Qt}
Stationary Distribution: \pi Q = 0, \sum_{j} \pi_{j} = 1
Birth-Death Process: At state k, \lambda_k, \mu_k
are birth and death rates. Transition Matrix: Q =
 \begin{bmatrix} -\lambda_0 & \lambda_0 & 0 & 0 & \cdots & \cdots \\ \mu_1 & -(\lambda_1 + \mu_1) & \lambda_1 & 0 & \cdots & \cdots \\ 0 & \mu_2 & -(\lambda_2 + \mu_2) & \lambda_2 & 0 & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \end{bmatrix}
Equilibrium Solution: \pi Q = 0 and \sum_j \pi_j = 1
Differential Difference Equations: \frac{\partial \pi_k(t)}{\partial t} =
\begin{array}{l} \lambda_{k-1}\pi_{k-1}(t) + \mu_{k+1}\pi_{k+1}(t) - (\lambda_k + \mu_k)\pi_k^{\partial t}(t) \\ \frac{\partial \pi_0(t)}{\partial t} = \mu_1\pi_1(t) - \lambda_0\pi_0(t) \end{array}
\frac{\partial t}{\partial \pi_k(t)} = \text{flow in - flow out}
flow in = \lambda_{k-1}\pi_{k-1} + \mu_{k+1}\pi_{k+1}
flow out = (\lambda_k + \mu_k)\pi_k
Queueing Theory: Analyze different systems.
Poisson distribution model arrival process,
exponential distribution model service times.
Poisson Process: ArrivalRate of \lambda:
p(n \text{ arrivals in interval } T) = \frac{(\lambda T)^n e^{-1}}{n!}
Exponential Inter-Arrival Time:
p(\text{inter-arrival} \le T) = 1 - e^{-\lambda T}
Merging Property: Let A_1, A_2, ..., A_k be
independent Poisson processes with rates \lambda_1, \lambda_2, ...,
\lambda_k, then A=\sum_i A_i is also Poisson process with
rate \lambda = \sum_{i} \lambda_{i}
Splitting Property: Suppose every arrival is
randomly routed with probability p to stream 1 and
(1-p) to stream 2. Stream 1 and 2 are Poisson
with rates p\lambda and (1-p)\lambda.
Kendall's Notation: A/B/C/D
A: inter-arrival time distribution
B: service time distribution
C: number of servers
D: maximum number of jobs possible
M:exponential, D: deterministic, G: general
\alpha(t): number of arrivals in (0, t)
\beta(t): number of departures in (0, t)
N(t): number of customers in system at t
T(t): average time in system for customer up to t
N: average number of customers in system.
N = N_q + N_s
T: average waiting time in system. T = T_q + T_s
Little's Law: N = \lambda T
Utilization Factor (Traffic Intensity Factor):
\rho = \text{Work Arrival Rate} / \text{Server Capacity}
System is unstable if \rho > 1
Single Server System
\rho is fraction of time server is busy
Multi-Server System
\rho is fraction of busy servers
M/M/1 Model: Assume state independent
arrival \lambda, service rate \mu. At equilibrium, flow in =
flow out, \lambda \pi_0 = \mu \pi_1 \to \pi_1 = \frac{\lambda}{\mu} \pi_0, \, \pi_1 = \rho \pi_0.
Similarly \lambda \pi_2 = \rho \pi_1 = \rho^2 \pi_0. In general \pi_n = \rho^n \pi_0. \sum_i \pi_i = 1 \to \pi_0 = 1 - \rho, \pi_n = (1 - \rho)\rho^n
Average Number Customers in System N:
\sum_{k} k \pi_{k} = \sum_{k} k (1 - \rho) \rho^{k} = \frac{\rho}{1 - \rho} = \frac{\lambda}{\mu - \lambda}
Average Time in System T
T = N/\lambda (with Little's Law), T = \frac{1}{\mu - \lambda}
Average Time in Queue T_q: T_q = T - T_s = \frac{1}{\mu - \lambda} - \frac{1}{\mu}
```

Average Number of Customers in Queue:

**Discouraged Arrivals**: Arrival rates decrease with customers in system,  $\lambda_k = \frac{\alpha}{k+1}$ ,  $\mu_k = \mu$ 

 $N_q = \lambda T_q = N - \rho$  (with Little's Law)

Equilibrium state, 
$$p_k=p_0(\frac{\alpha}{\mu})^k\frac{1}{k!}$$
. Since  $\sum_{k=0}^{\infty}p_k=1$  we find that  $p_0=e^{-\alpha/\mu}$ . So  $p_k=((\frac{\alpha}{\mu})^ke^{-\frac{\alpha}{\mu}})/k!$ . Utilization  $\rho=1-p_0=1-e^{-\frac{\alpha}{\mu}}$ 

Expected number of customers in system:  $N = E[k] = \alpha/\mu$ . Expected time in system  $T = N/\lambda$ .  $\lambda_{\text{eff}}$  is expected (effective) arrival rate,  $\lambda_{\text{eff}} = \mu \rho = \mu (1 - e^{-\alpha/\mu}), \text{ so } T = \alpha/\mu^2 (1 - e^{-\alpha/\mu})$ M/M/∞ Model: Service rate (number of servers) scales linarly with number of customers in system.  $\rightarrow$  No waiting time, served immediately.  $\lambda_k=\lambda$ ,  $\mu_k=k\mu$ . Equilibrium state,  $p_k=(\frac{\lambda}{\mu})^ke^{-\lambda/\mu}/k!$ ,  $p_0 = e^{-\lambda/\mu}$  (same as discouraged arrival system). Expected number of customers  $N = E[k] = \lambda/\mu$ .

M/M/m Model: Unlimited waiting room, constant arrival rate  $\lambda$ , maximum of m servers. Each server has service rate  $\mu$ .  $\lambda_k = \lambda$ ,  $\mu_k = k\mu$ (k < m),  $m\mu$   $(k \ge m)$ . Equilibrium distribution,  $p_{k} = \frac{(m\rho)^{k}}{k!} p_{0} (k < m), \frac{(m\rho)^{k}}{m!} \frac{1}{m^{k-m}} p_{0} (k \ge m)$ where  $\rho = \lambda/m\mu$ . When  $\rho < 1$ ,  $p_{0} = \left[\sum_{k=0}^{m-1} \frac{(m\rho)^{k}}{k!} + \frac{(m\rho)^{m}}{m!(1-\rho)}\right]^{-1}$ 

Expected time in system  $T = N/\lambda = 1/\mu$ 

M/M/1/K Model: System has single server and maximum of K customers. Equilibrium state,  $p_k = p_0(\frac{\lambda}{\mu})^k \ (k \leq K), \ 0 \ (k > K), \text{ where}$  $p_0 = \left(1 - \frac{\lambda}{\mu}\right) / \left(1 - \left(\frac{\lambda}{\mu}\right)^{K+1}\right)$ 

Finite Population Systems: World has finite users and each user is either in system or to arrive with exponential time with mean  $1/\mu$ .

 $\lambda_k = \lambda(M-k) \ (0 \le k < M), \ 0 \ (\text{otherwise}). \ \mu_k = \mu$  $(1 \le k \le M)$ , 0 (otherwise). Equilibrium state,  $p_k = p_0(\frac{\lambda}{\mu})^k \frac{M!}{(M-k)!} \ (0 \le k \le M), \ 0 \ (\text{otherwise}).$ 

$$p_0 = \left[ \sum_{k=0}^{M} \left( \frac{\lambda}{\mu} \right)^k \frac{M!}{(M-k)!} \right]^{-1}$$

**Q0**: Using Laplace Transform, solve differential equations  $x(t) = \frac{dx(t)}{dt} + 2\frac{d^2x(t)}{dt^2}$ , x(0) = 1, x'(0) = 1/2.

$$\begin{split} &L\{x'(t)\} = sX(s) - x(0) \\ &L\{x''(t) = s^2X(x) - sx(0) - x'(0)\} \\ &X(s) = sX(s) - x(0) + 2[s^2X(x) - sx(0) - x'(0)] \\ &X(s) = 1/(s - \frac{1}{2}), \, x(t) = e^{1/2t} \end{split}$$

Q1: Program has execution time uniformly distributed between 10 & 20 seconds. Number of interrupts during execution is Poisson random variable with parameter  $\lambda t$  where t is program execution time. Probability distribution of the number of interrupts is  $P(N=k) = (\lambda t)ke^{\lambda t}$ .

(a) What is E[N|T=t], where N is the number of interrupts, and T is running time.

 $E[N|T=t]=\lambda t$ , since for fixed running time, the number of interrupts is a Poisson random variable with mean  $\lambda t$ .

(b) Expected number interrupts during randomly selected execution.

$$E[N] = \int_{10}^{20} E[N|T=t] f_T(t) dt = \int_{10}^{20} \frac{\lambda t}{10} dt = 15\lambda$$

 $\mathbf{Q2}$ : We have m types of visitors with equal probability. Find expected visitors to have one of each type. Hint: Let X denote number of visitors needed. Represent X by  $X = \sum_{i=1}^{m} X_i$  where each  $X_i$  is a geometric random variable.

Suppose the current visitor pool contains i different types. Let  $X_i$  denote the number of additional visitors needed until it contains i + 1 types. The  $X_i$ is are independent geometric random variables with parameter (m-i)/m,  $i=0,1,\cdots,m-1$ .  $E[X]=E[\sum_{i=1}^m X_i]=\sum_{i=1}^m E[X_i]=\sum_{i=1}^m \frac{m}{m-i}$ 

**Q3**: A Markov chain  $\{X_n, n \geq 0\}$  with states 0, 1, 2 has transition probability matrix

$$\begin{bmatrix} 1/2 & 1/3 & 1/6 \\ 0 & 1/3 & 2/3 \\ 1/2 & 0 & 1/2 \end{bmatrix} \text{ If } P[X_0 = 0] = P[X_0 = 1] = \frac{1}{4},$$
find state probability vector  $P[X_0 = 2]$ 

find state probability vector  $P[X_3 = 2]$ .

Cubing transition probability matrix

$$P^{(3)} = \begin{bmatrix} 13/36 & 11/54 & 47/108 \\ 4/9 & 4/27 & 11/27 \\ 5/12 & 2/9 & 13/36 \end{bmatrix}$$

$$P[X_3 = 2] = \frac{1}{4} \cdot \frac{47}{108} + \frac{1}{4} \cdot \frac{11}{27} + \frac{1}{2} \cdot \frac{13}{36}$$

 ${f Q4}$ : Whether or not collision occurs depends on result of last two transmissions If collisions occurred in both of the past two, collision will occur with probability 0.7; collision occurs in last but not the transmission before the last one, then a collision will occur with probability 0.5; collision occurred in transmission before the last one but not the last one, collision with probability 0.4; no collision in the past two transmissions, collision with probability 0.2.

(b) Find the transition probability matrix.

$$P = \begin{bmatrix} 0.7 & 0 & 0.3 & 0 \\ 0.5 & 0 & 0.5 & 0 \\ 0 & 0.4 & 0 & 0.6 \\ 0 & 0.2 & 0 & 0.8 \end{bmatrix}$$

(c) What fraction of frames suffer a collision? Solve  $\pi = \pi P$  to obtain the stationary state probabilities. Then the fraction of frames suffering a collision is  $\pi_0 + \pi_2$  (or  $\pi_0 + \pi_1$ ).

Q5: A shop has room for 2 customers. Customers arrive at Poisson rate 3/hour and service times are exponential random variables with mean 0.25 hours.

(a) Average number of customers in shop? We have birth-death process with  $\lambda = 3$  and  $\mu = 4$ .  $E[k] = \sum_{k=0}^{2} k \pi_k$ . Solve for  $\pi_k$ ,  $\pi_1 = \frac{\lambda}{\mu} \pi_0$ ,  $\pi_2 = \frac{\lambda}{\mu} \pi_1, \sum_{j=0}^{2} \pi_j = 1$ , so  $\pi_0 = 16/37$ , E[k] = 30/37.

(b) What is proportion of customers who get serviced?  $\pi_0 + \pi_1 = 28/37$ .

Q6: Packets arrive at router Poisson rate 3/ms and time to foward exponential with mean 0.2 ms. Fraction of time buffer empty?

State is num packets in router,  $\lambda=3,\,\mu=5.$  Solve  $p_1=\frac{\lambda}{\mu}p_0,\,p_2=\frac{\lambda}{\mu}p_1,\,...,\,p_{k+1}=\frac{\lambda}{\mu}p_k,$   $\sum_{k=0}^{\infty}p_k=1,$  thus  $p_0=2/5.$ 

 $\mathbf{Q7}$ : 2 machines produce products at nproducts/hour. Lifetime of machine follows exponential with mean 1/x hours, time to fix machine follows exponential with mean 1/y hours. Expected long term producing rate?

State is num machines working.  $\lambda_0 = \lambda_1 = y$ ,  $\mu_1 = x$ ,  $\mu_2 = 2x$  be if either machine fails, num working machines reduce from 2 to 1. Solve  $\begin{array}{l} p_1=\frac{y}{x}p_0,\,p_2=\frac{y}{2x}p_1,\,p_0+p_1+p_2=1,\,\text{thus}\\ p_0=\frac{2x^2}{2x^2+2xy+y^2}.\,\,\text{Expected num products}\\ \text{produced per hour:}\,\,p_0\times 0+p_1\times n+p_2\times 2n \end{array}$ 

Q8: M/M/1 queueing system. Jobs arrive to be scheduled at rate  $\lambda$  jobs/ms. Single core serving jobs at rate of  $\mu$  jobs/ms. Suppose that the we want the average time spent in waiting queue to be no more than 3 milliseconds. If  $\lambda = 10 \text{ jobs/ms}$ , find minimum of  $\mu$ .

Steady state probabilities are  $\pi_0 = 1\rho$ ,  $\pi_k = \rho^k(1\rho)$ where  $\rho = \lambda/\mu$ . Average customers  $N = \frac{\rho}{1-\rho}$ . By Little's Law,  $N = \lambda \cdot T \to T = N$  where T is average time in system. Average waiting time  $W = T - 1/\mu, \text{ so we need}$   $W = \frac{\rho}{\lambda(1-\rho)} - \frac{1}{\mu} = \frac{1}{\mu-\lambda} - \frac{1}{\mu} \le 3$ 

 $\mathbf{Q9}$ : M customers go to single-server. When customer arrives, enters service if the server is free or joins queue. Upon leaving, customer returns after exponential time with rate  $\lambda$ . Service time exponentially distributed  $\mu$ .

(a) Define states and set up the balance equations. States are # customers in server. Balance equations  $M\lambda\pi_0 = \mu\pi_1$  $((M-i)\lambda + \mu)\pi_i = (M0i+1)\lambda\pi_{i-1} + \mu\pi_{i+1}$  for  $i=1,2,\cdots,M-1$ 

(b) Average rate customers enter the station.

 $\lambda_{\text{avg}} = \sum_{i=0}^{M} (M-i)\lambda \pi_i$ 

(c) Average time customer spends. Avg # customers  $N = \sum_{i=0}^{M} i\pi_i$ . Avg time  $T = N/\lambda_{\text{avg}}$ 

Q10: UCLA receives 10 average applications. Each has 0.7 probability getting accepted. Program takes 2 years. Assume Poisson arrival, exponential time for time length.

What is probability no students in program? What is average number of students in program each

Modeled as  $M/M/\infty$  system with  $\lambda = 10 \cdot 0.7 = 7$ ,  $\mu = 0.5$ . No students in program:  $p_0 = e^{-\lambda/\mu}$ Average number of students  $N = \lambda/\mu = 14$ .

Q11: Two servers. 90 reqs/hour and placed in single buffer one server becomes free. Service time 1.2 minutes. Assuming inter-arrival times and service times exponential. Determine probability no requests in the system. Expected number of requests in the system. Expected time request waits in buffer.

Modeled as M/M/2 with  $\lambda = 90, \, \mu = 50.$  $\rho = \lambda/\mu = 1.8$ .  $\rho/m = 1.8/2 = 0.9 < 1$ . Thus system is stable. P[No Requests]

$$= \left[\frac{\rho^m}{m!} \frac{m}{m-\rho} + \sum_{n=0}^{m-1} \frac{\rho^n}{n!}\right]^{-1}. \text{ Expected number of reqs, } N_s = \sum_{n=0}^{\infty} np_n = \sum_{n=0}^{m-1} np_n + \sum_{n=m}^{\infty} np_n, \\ N_s = \sum_{n=0}^{m-1} n \frac{p^n}{m!} p_0 + \sum_{n=m}^{\infty} \frac{p_n}{m!m^{n-m}p_0}. \\ \text{ Expected time in buffer, } T_q = T_s - 1.2(\text{min}), \text{ where } T_s = N_s/\lambda. \ T_q = 5.117 \text{ (min)}.$$
